Cell Reproduction: In Honor of Daniel Mazia represents the proceeding of a symposium entitled "Cell Reproduction held in Keystone, Colorado, on March 1978. The symposium is organized to honor Daniel Mazia. Most of the areas of research that are discussed at the conference have their origins in Dan Mazia's laboratory. This volume is divided into nine parts, consisting of papers presented in the symposium. It first focuses on the macromolecular control in cell proliferation and growth, cell cycle regulation, control of genetic expression, and microtubule assembly in vitro and in vivo. It then explains the control of fertilization phenomena, chromosome movement, the mitotic apparatus, and control of cell division and cell cleavage. Lastly, this volume discusses the structural and molecular basis of cell movement and describes the differentiated cell. This book represents a tribute to Daniel Mazia's extraordinary contributions as teacher, scientist, and friend.

The Bacterial Cell: Coupling between Growth, Nucleoid Replication, Cell Division and Shape

Theoretical Systems in Biology: Hierarchical and Functional Integration, Volume I: Molecules and Cells covers the molecular and cellular aspects of classical biology. The book is comprised of 12 chapters, which are organized into three parts. Part I covers topics relating to the materials and methods in biological dynamics, such as macromolecular components and interactions, chemistry of cells, and biological dynamics. Part II deals with the molecular organization of living matter; this part covers the organization of biological systems and the relationship between evolution and physiology. Part III talks about issues concerning the cellular organization of living matter, such as regulation of cell function, cell growth, and cell division. The book will be of great use to biologists concerned with the theoretical systems in biology, specifically in cells and molecules.

Controlled expansion of cell populations is a fundamental feature of living organisms, being a finely-tuned balance between cell proliferation and cell death. This book aims to explain the molecular mechanisms that lie behind the multiplication and survival of eukaryotic cells. This encompasses both the normal regulation of cell populations in development or physiological adaptation and pathological mechanisms of cell cycle control in cancer. Principles of Cell Proliferation progressively introduces the function of growth factors, receptors, signal transduction pathways, gene expression and the conserved mechanisms of the cell cycle engine. This provides a context for understanding the mechanistic consequences of the genetic alterations in oncogenes and tumour suppresser genes which underlie tumour formation. The book should satisfy advanced level courses in Cell Proliferation, Cell Cycle Control and Cancer Biology for biologists, biochemists and medical students. The book comes at a time when the underlying molecular mechanisms of cancer are beginning to be unravelled. Ideal for advanced level courses in Cell Proliferation, Cell Cycle or Cancer Biology. An accessible account of a subject many students find complex.

Now in its second year, Progress in Cell Cycle Research was conceived to serve as an up to date introduction to various aspects of the cell division cycle. Although an annual review in any field of scientific investigation can never be as current as desired, especially in the cell cycle field, we hope that this volume will be helpful to students, to recent graduates considering a delimitation in subject and to investigators at the fringe of the cell cycle field wishing to bridge frontiers. An instructive approach to many subjects in biology is often to make comparisons between evolutionary distant organisms. If one is willing to accept that yeast represent a model primitive eukaryote, then it is possible to make some interesting comparisons of cell cycle control mechanisms between mammals and our little unicellular cousins. By and large unicellular organisms have no need for intracellular communication. With the exception of the mating phenomenon in *S. cerevisiae* and perhaps some nutritional sensing mechanisms, cellular division of yeast proceeds with complete disregard for neighbourly communication. Multicellular organisms on the other hand, depend entirely on intracellular communication to maintain structural integrity. Consequently, elaborate networks have evolved to either prevent or promote appropriate cell division in multicellular organisms. Yet, as described in chapter two the rudimentary mechanisms for fine tuning the cell division cycle in higher eukaryotes are already apparent in yeast.

This volume introduces some basic mathematical models for cell cycle, proliferation, cancer, and cancer therapy. Chapter 1 gives an overview of the modeling of the cell division cycle. Chapter 2 describes how tumor secretes growth factors to form new blood vessels in its vicinity, which provide it with nutrients it needs in order to grow. Chapter 3 explores the process that enables the tumor to invade the neighboring tissue. Chapter 4 models the interaction between a tumor and the immune system. Chapter 5 is concerned with chemotherapy; it uses concepts from control theory to minimize obstacles arising from drug resistance and from cell cycle dynamics. Finally, Chapter 6 reviews mathematical results for various cancer models.

Puck discusses the methods of deriving cultures from single animal cells; R. Dulbecco, problems of virus reproduction; and R. M. Klein, the current status of cultivating plant tissues. D. M. Prescott then examines the rhythmic growth and division of Amoebae; C. S. Pittendrigh and V. G. Bruce contribute a review of their analysis of internal clocks in animals; and E. Bunning writes on diurnal rhythms in vascular plants. Finally H. Gaffron and B. L. Strehler discuss the origin, significance and mechanics of photosynthesis while H. F. Blum and H. Shapley take up other aspects of biochemical evolution. Originally published in 1957. Bacterial Physiology was inaugurated as a discipline by the seminal research of Maaløe, Schaechter and Kjeldgaard published in 1958. Their work clarified the relationship between cell composition and growth rate and led to unravel the temporal coupling between chromosome replication and the subsequent cell division by Helmstetter et al. a decade later. Now, after half a century this field has become a major research direction that attracts interest of many scientists from different disciplines. The outstanding question how the most basic cellular processes - mass growth, chromosome replication and cell division - are inter-coordinated in both space and time is still unresolved at the molecular level. Several particularly pertinent questions that are intensively studied follow: (a) what is the primary signal to place the Z-ring precisely between the two replicating and segregating nucleoids? (b) Is this coupling related to the structure and position of the nucleoid itself? (c) How does a bacterium determine and maintain its shape and dimensions? Possible answers include gene expression-based mechanisms, self-organization of protein assemblies and physical principles such as micro-phase separations by excluded volume interactions, diffusion ratchets and membrane stress or curvature. The relationships between biochemical reactions and physical forces are yet to be conceived and discovered. This e-book discusses the above mentioned and related questions. The book also serves as an important depository for state-of-the-art technologies, methods, theoretical simulations and innovative ideas and hypotheses for future testing. Integrating the information gained from various angles will likely help decipher how a relatively simple cell such as a bacterium incorporates its multitude of pathways and processes into a highly efficient self-organized system. The knowledge may be helpful in the ambition to artificially reconstruct a simple living system and to develop new antibacterial drugs.

Mitosis is the process by which cells, after having duplicated their DNA content, segregate chromosomes equally into two identical daughter cells. Mitosis is a very short part of a normal cell cycle (usually 24+hours) and ranges from 30 minutes to an hour depending on cell type and environmental conditions. During this incredibly short amount of time, the cell undergoes several complex re-arrangements, biomechanically and biochemically. Microtubules, 20 nm width dimer polymers, play an essential role as the building blocks that provides the cytoskeleton and mitotic spindle for the cell, provide the force that segregates chromosomes (anaphase), to satisfaction of tension and attachment based checkpoints (metaphase-anaphase transition). To elucidate the key role microtubules have in mitosis, drugs such as taxol and nocodazole have been used to impart catastrophic global damage to the mitotic spindle and study the effects on cellular division. However, catastrophic global damage can not answer specific questions regarding highly spatially localized damage and temporally transient damage. In elucidating the role of microtubules, chromosomes and other key biological structures, there is the need for a transient perturbation on the mitotic process. To study the effects of transient perturbation on mitosis, a Laser microscope system (Robolase) was developed to deliver spatially localized (~0.4 um) and temporally-specific disruption inside living cells (nanosurgery). Specifically, the affect of ablating chromosome tips, mitotic spindles, and chromatid are examined, and the relationship between damaged sites and pathways controlling the progression of the cell cycle and DNA damage pathways are examined. In conclusion, an optically based method for studying mitosis with transient perturbation has been developed and used to determine that chromosome tip disruption affects cytokinetic progression, prolonged disruption of mitotic spindle reveals force sensing in the metaphase spindle, and double-strand breaks of DNA recruit CENP-A in addition to known DNA damage proteins.
